JUICES AND SMOOTHIES

INTRODUCTION

High Pressure Processing (HPP) is a non-thermal food processing technology that allows for juices and smoothies made with fruits and vegetables to obtain a longer shelf life, while preserving nutrients and the fresh taste. On this sector of juices and beverages, the pressure range used is between 400 MPa (58000 psi) and 600 MPa (87000 psi), and it is typically applied from few seconds to 5 minutes at refrigerated or room temperature.

Regarding to a physico-chemical effect on food, the HPP technology is softer than a thermal treatment: it does not break or create covalent bonds, and does not create new compounds by molecule degradation, such as in a conventional thermal process. However, HPP is able to break, or create, weak bonds (hydrophobic and electrostatic interactions,...), only present on macromolecules (Cheftel, 1992). It allows microorganism inactivation without modifying the food nutritional quality and without significantly reducing enzymatic activities. To minimize the enzymatic changes and residual microorganism growing, juices must be stored at chilled temperature.

There are three reasons that make the HPP technology beneficial:

- Longer shelf-life and safer food products are launched, thanks to the inactivation of vegetative microorganisms (bacteria, yeasts and molds).
- Sensorial food quality is not modified.
- Nutritional quality is preserved.
FOOD SECURITY AND LONGER SHELF-LIFE

Shelf-life could be multiplied from 3 up to more than 10 times comparing with the same product without HPP, stored at same temperature. HPP can also assure 5-log reduction of pathogens in beverages.

Shelf-life increase

Orange juice

HPP reduces the microbial load to non-detectable levels immediately after processing of juices made of Navel and Valencia varieties (Bull et al., 2004). Storage of the juices (pH=3.55) at 4ºC (39ºF) kept the microbial load below 2 log cfu/ml for up to 12 weeks. The total aerobic population of HPP orange juice (600 MPa, 60 s) kept steady during 30 days of storage time (Timmermans et al., 2011).

Reduction of total microflora depends on holding time at high pressure, as shown by Erkmen et al. (2004) in the case of orange and peach juices (Figures 1 and 2).

Peach juice

High pressure processing reduces total aerobic population up to 7 log cycles in peach juice (pH 5.21) depending on the processing time at 600 MPa. (Figure 2)

Coconut water

Processing this natural isotonic drink at 600MPa during 180 s, allows to achieve 60 days shelf-life, stored at 4ºC (39ºF), and with a microbial aerobic total count less than 10 cfu/ml when the initial contamination is around 1000 cfu/ml. (Hiperbaric, unpublished, 2012)

Challenge tests

Challenge tests performed by Teo et al. (2001) for evaluating the inactivation of Salmonella enteritidis and E. coli in orange, grape, and carrot juices showed differences, nevertheless a reduction of more than 5 log is achieved for all juices when processed at 600 MPa (6000 bar/ 87,000 psi) during 2 min (Table 1).

Aspects to consider

Microbial inactivation levels depend on the pressure and holding time as well as other factors such as water activity ($a_w$) or pH.

The lower water activity ($a_w$) (or higher Brix degrees) the lower effectiveness high pressure is (P. Oxen and D. Knorr, 1993; E. Goh et al., 2007); therefore, the technology is very effective on fresh-squeezed juices allowing them reach several months of shelf-life at refrigerated temperature, but not on concentrated juices with a ºBrix higher than 40 (Oxen and Knorr, 1993).

The pH of a product is also a key factor to consider, working in synergy with HPP: the lower pH a product has, the more effective microbial inactivation by HPP is reached.

HPP does not inactivate bacterial spores (but mold spores are inactivated). Regarding HACCP, HPP cannot be used to control *Clostridium botulinum* or any other bacterial spore.

Juices with a pH>4.6 are at risk for spore germination and therefore they must be kept refrigerated for the entire life of the product. We recommend acidifying juice products to a pH <4.6 whenever possible to prevent spore germination. Low pH-fruit juices (pH < 4.6) could be microbiologically stable at room temperature, since their low pH values avoid spore germination.

SENSORY QUALITY

Many sensorial studies reinforce that the HPP juices have similar characteristics as the fresh ones. The differences between a fresh orange juice and an HPP orange juice are not significant, as we can see on the following Figure 3 (Matser et al., 2012).

As occurs with the fresh juice, the sensorial quality is variable depending on the fruit variety. Regarding to orange juice, the “Valencia Late” variety has a better flavor profile than others.

With exception of orange juice, the consumers are unaware about the fresh juices flavor: because if they have tasted pasteurized or sterilized fruits juices. That is the reason why most of the studies are focusing on HPP juice sensory evaluation and not comparing them with a fresh one.

On the grape juice sensory study developed by Moreno et al. (2013) to evaluate color, smell, sweetness, flavor and overall quality, most of the consumers qualified the HPP juice as a good taste (Figure 4).
NUTRIENTS RETENTION

The high nutrient retention level related to the high hydrostatic pressure processing, has made possible the development of functional juices and drinks (watermelon, broccoli, pomegranate or blueberry for example), which would not have been possible with another technology: because of a short shelf-life which does not allow to entry in distribution channels or because the other preservation treatments destroy the nutrients that gives them the antioxidant or antimutagenic functional properties.

Antioxidants: vitamins and polyphenols.

Polyphenols. Ferrari et al. (2010) and Liu et al. (2013) showed that HPP technology held pomegranate and watermelon juices high phenolic compound content almost as the fresh juice (Figure 5).

Antioxidants. Moreno et al. demonstrate in black grape juice that the contents of polyphenols and antioxidants are similar between HPP and not processed (Figure 6).

The content of ascorbic acid (vitamin C), after high pressure processing is practically unaffected by high pressure processing as Queiroz et al. (2010) demonstrated in cashew apple juice. Watermelon juice retains lycopene after HPP processing. Even though, watermelon juice processed at high intensive HPP conditions (600 MPa / 87,000 psi for 15 min) retains around 98% of lycopene content compared to fresh juice (Liu et al., 2013).

Ascorbic acid is very sensitive to heat treatment thus HPP is a quite suitable technology for maintaining this nutritional compound.

Antimutagens

Broccoli is a vegetable that has a high concentration of antimutagenic molecules such as sulphoraphane, indol-3-carabinol o glucosinolates. As they are all thermolabile molecules, the thermal process of broccoli induces a large or total loss of activity of this compound type. The HPP process is a perfect method to maintain these properties intact (Mandelova et al., 2007).

Figure 5: Retention of polyphenols in pomegranate (Ferrari et al. 2010) and watermelon juices after HPP processing (Liu et al., 2013).

Figure 6: Polyphenols content and color parameters in HPP black grape juice (600 MPa, 7 min) and control (Moreno et al., 2013).
Evolution of nutrients post HPP processing

Nutrient retention immediately after high pressure processing is an important benefit of HPP technology, but it is important keeping these nutrients during the whole product shelf-life.

Figure 7 shows the evolution during storage of the relative content of vitamin C in HPP processed blueberry juice and not processed juice. High pressure processing minimizes vitamin degradation through time in comparison to fresh juice (Barba et al. 2012).

Table 2 shows the content of vitamin C, phenolic compounds and anthocyanin in blueberry juice. The content of these compounds is similar in HPP and untreated sample. At day 0, concentration of vitamin C is slightly higher in unprocessed samples. However, HPP-processed juice maintains the content of these nutritional-related molecules throughout the storage (up to 56 days).

CONCLUSIONS

Since the first high-pressure-processed juice was launched in early 90’s in Japan and Europe; and in USA in the beginning of 21 century, HPP fruit juices and smoothies start a continuous growth. During last few years, the number and volume of HPP beverages has significantly increased.

The effectiveness of high hydrostatic pressure for increase the shelf-life and safety of those beverages and, at the same time, maintaining its nutritional and sensory quality, has allowed for the expansion of HPP technology within the juices and smoothies industry.

A reflection of this is the growth of the number of our customers as such as this link shows: http://www.hiperbaric.com/en/customers
